

October 2018

Description

The FDY PC-Programmable Frequency-to-DC Transmitter with Display monitors frequency, period, high or low pulse width, and contact closure signals. It converts the input signal to a proportional, input-to-output isolated 4-20mA output ready for direct interface with a readout instrument, recorder, PLC, DCS, SCADA system or other readout instrument.

The 2-wire (loop-powered) FDY is ideal for use in a wide range of process and factory automation monitoring applications:

- Turbine Tachometer Generators
 - Turbine Flow Meters
- Magnetic Pickups • Dry Contact Closures
- Variable Frequency Drives • Rotating Equipment
 - Pulse and Frequency Output Transducers
 - Motor and Conveyor Speed

The FDY installs quickly and easily in harsh conditions using our protective field-mount enclosures, or on a surface, DIN-rail or relay track.

Figure 1. The FDY configures with application-specific operating parameters in just minutes using our single-window Intelligent PC Configuration Software

Features

- **Exceptional accuracy and long-term stability.** Typical accuracy is $\pm 0.025\%$ of span with up to 5 years between scheduled calibrations.
- **Sets up in minutes with PC software.** You can choose, and then view to confirm, all application-specific operating parameters.
- **Versatile input choices.** Measures frequency ranges between an amazingly low 0.005Hz up to 25kHz; periods from 40microseconds to 200sec; and pulse widths from 0.2msec to 200 seconds.
- **User-configurable display.** A 5-digit LCD shows the process variable in selectable engineering units.
- **Input-to-output isolated and RFI/EMI protected.** Resistant to unpredictable ground loops and the harmful effects of plant and equipment “noise”.
- **Programmable moving average filter.** Minimizes measurement instability caused by the effects of bent turbine blades and other frequency variations.

Accurate Frequency Monitoring

In power generating stations, stand-by power systems, and cogeneration plants, the frequency of the generated power must be tightly controlled.

The FDY provides extraordinary precision for this measurement, providing a 4-20mA signal for a narrow span centered on the set point (for example, 55-65Hz for a 60Hz system).

Figure 2. Precision frequency measurement for power generators

Make Consistent Flow Measurements

Flow measurements are often made with turbine flow meters. One common source of measurement inconsistencies is frequency variation due to bent blades.

Programmable Averaging Filter—To compensate for bent blades, the FDY incorporates a programmable moving average filter. The user-selectable moving average is set to match the number of turbine blades. Taking a reading from each turbine blade, the FDY averages the readings to produce a “smoothed out” 4-20mA value proportional to the continuous averaged measurement. This advantage stretches the time between maintenance

cycles needed to replace the rotor in the turbine meter by delivering accurate measurements even if the turbine blade(s) are damaged.

Custom Linearization Curves—Another potential for error is the effect of viscosity, which varies according to published curves. For liquids, the change is temperature related, while for gas, it is flow related. In some cases, the onboard linearization capability of the FDY can compensate for the viscosity effect using calibration data supplied by the meter manufacturer.

Figure 3. Programmable “filtering” features minimize the effects of bent turbine blades

Increasing Pump Efficiency

Natural gas typically must be processed both to remove unwanted contaminants, and to separate it into different types of gas before it is usable. These gas processing plants require the raw gas to be pumped from low pressure to high pressure to produce usable products. Maintaining consistent pump speed is essential to this process to maintain efficiency and decrease wasted product.

Most pumps use jet engines to create the required pressure; however, a change in engine speed of just $\pm 0.1\%$ can vary the volume of the pump drastically. To ensure the pump is operating at the required level, it must be continuously monitored.

To accomplish this, a magnetic pickup is attached to the pump shaft (Figure 4). The pickup provides a frequency output. The FDY takes the pickup signal, converts it to a 4-20mA output proportional to the pump shaft speed, and transmits it to the DCS. Should there be an unwanted change in speed, it can be detected at the DCS.

Because of the FDY's superior accuracy, it is able to detect even slight changes in shaft speed to help ensure the pump is running at optimum efficiency.

Figure 4. Monitor pump speed to ensure optimum efficiency

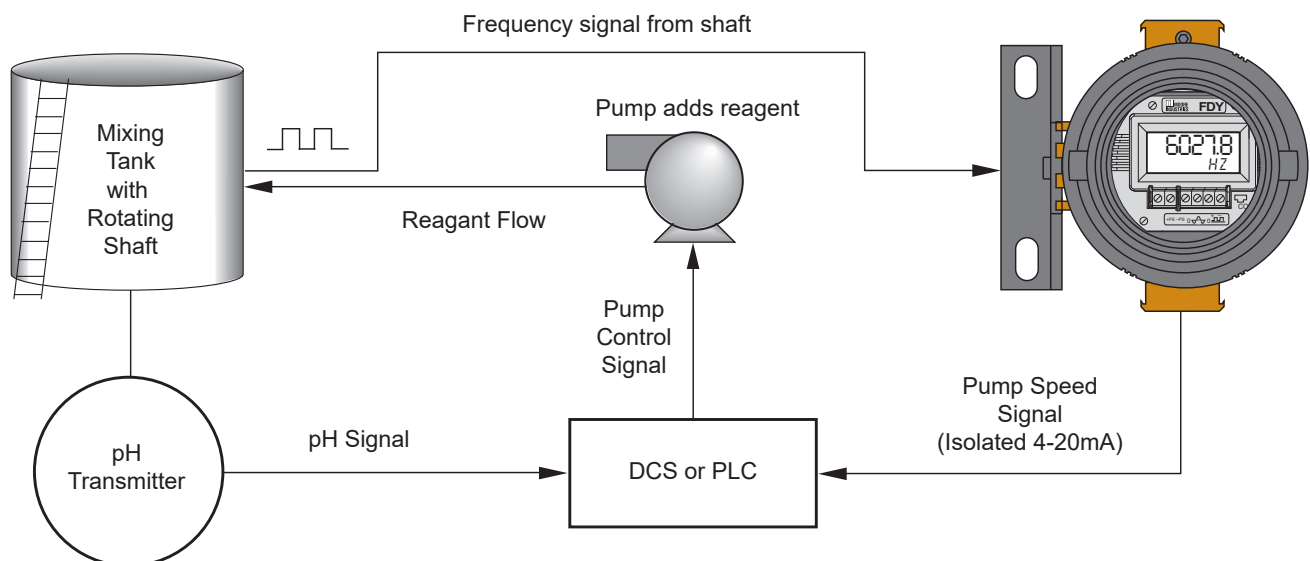

Measuring Volumetric Flow Based On Shaft Rotational Speed

Many processes require the periodic addition of precise amounts of a reagent or similar additives using a pump. Because there is a direct correlation between shaft rotation speed and the volume of product pumped, this strategy delivers a precise volume of additive for each revolution of the shaft.

In this application, the FDY is used to accurately measure the RPM of the shaft, and provide a 4-20mA signal directly proportional to volumetric flow (Figure 5). The flow information is used by the control system to provide on/off pump control.

Figure 5. Precision feedback of pump shaft revolutions per minute (RPM) for monitoring additive volume

FDY

Measuring Weight per Minute of Product Transported on Conveyor Belts

The FDY accepts the input from a magnetic pickup sensor, turbine tachometer generator, dry contact closure, or other frequency sensor. It converts the input to a user scaleable 4-20mA signal proportional to belt speed. This is useful for measuring and transmitting information from conveyor belts.

Mining and Cement Industries

The mining and cement industries often use conveyor belts to transport bulk solids. The amount of the product being moved is related to its cross sectional area, (determined by measuring the average height on the belt across a known width), the weight of the material, and the speed of the belt. (Typically, a non-contact device is used to measure the average height and provide a 4-20mA signal.)

A weighing system accepts the analog inputs for height and speed and makes the calculations for weight per minute. Moore Industries' MDS I/O Equation Station may be used to provide this calculation functionality and then report the information to a monitoring system via 4-20mA signal, discrete status and/or MODBUS RTU data.

Paper Industry

In most paper production facilities, precision control of roller speeds is critical. Use the FDY to make a speed measurement using a frequency pickup on the roller shaft. Installed in Moore Industries' NEMA 4X (IP66) D-BOX enclosure or an explosion-proof BH enclosure, the FDY can be field-mounted in rugged and hazardous field environments.

Figure 6. Used in conjunction with a weighing system, the FDY can be used for conveyor belt weight calculations
